

FluCov Bulletin – end-December 2022

FluCov project: combining data from around the world to better understand the impact of COVID-19 on influenza activity

Commentary

Contents

It has been three years since a cluster of atypical pneumonia cases in Wuhan, China, was reported to the World Health Organization (WHO) (January 1, 2020) that was later linked to the new **SARS-CoV-2** virus. The FluCov Bulletin provides an overview of the number of positive cases of **influenza** and **SARS-CoV-2** and the percentage of specimens that tested positive from January 2019 onwards in 22 countries across most regions of the world (see page 4).

Results

Globally, **influenza** circulation remains high and the peak has surpassed total detections during the winters of 2019/20, 2020/21 and 2021/22 (see Figure 1). The following patterns have been observed for **influenza** in December (until week 52):

- Increased **influenza** activity was reported in **France, Germany, Israel, Poland, South Korea, and the United Kingdom**.
- **Spain and Italy** also reported increased **influenza** activity, but the peak may have been reached.
- Although seasonal **influenza** activity remains high in North America (**Canada, Mexico and the United States**), it has started to decrease in these countries.
- **Influenza A** is currently the dominant circulating virus: when subtyped, most countries reported **influenza A(H3)** was dominant.
- The **Netherlands** and the **United Kingdom**, reported a mix of **influenza A(H3)** and **A(H1N1)pdm09**. In the Netherlands, influenza B has also been detected (26% of total detections in week 49).
- In Israel **influenza A(H1N1)pdm09** is dominant.
- Very little **influenza** activity was reported by the Southern Hemisphere countries covered in the Bulletin: **Australia, Brazil and South Africa**.
- Relatively low **influenza** activity was also observed in **China, Thailand, Japan, India and the Philippines**.

In most countries covered by the Bulletin, the decline in **SARS-CoV-2** detections that has been seen since August 2022 has leveled off and some countries are seeing increased activity. The following patterns were observed for **SARS-CoV-2** in December (week 52):

- Increased **SARS-CoV-2** activity was reported in **Brazil, Mexico, Japan and South Korea** during the second half of December.
- Some **SARS-CoV-2** activity was also reported in **France, Germany, Italy and Australia**. However, in these countries the number of detections is decreasing again.
- In **China**, weekly **SARS-CoV-2** detections seem to be decreasing sharply, however, this may be influenced by non-reporting or a reporting delay.

- Relatively low **SARS-CoV-2** activity has been reported in most of the other countries covered by the Bulletin (**United States, Canada, United Kingdom, Poland, Netherlands, Philippines, Spain, South Africa, India, Thailand, Israel, Vietnam**).

Implications

The 2022/23 Northern Hemisphere **influenza** season has started very early this winter, with increased activity in the **United States, Canada, Germany, Spain** and **Mexico**. A peak in **influenza** activity has been reached in these countries around week 49, and activity has started to decrease. Other Northern Hemisphere countries, mainly in Europe, are seeing an increasing number of **influenza** detections. Importantly, the peak of total detections in December 2022 (see Figure 1) has surpassed the peak of the previous three winters (2019/20, 2020/21 and 2021/22); this may be associated to increased influenza testing during the pandemic, and will need to be assessed further.

At the moment (week 52), when subtyping is performed, influenza detections are dominated by **influenza A(H3)**. No **influenza B(Yamagata)** activity has been observed in the last weeks and **influenza B(Yamagata)** has been nearly absent since the start of the **SARS-CoV-2** pandemic [1].

SARS-CoV-2 activity is particularly high in a number of Asian countries (**China, Japan, and South Korea**). Importantly, **China** is currently experiencing the worst **SARS-CoV-2** wave since the beginning of the pandemic. The observed decrease in **SARS-CoV-2** activity in **China** may be influenced by non-reporting, delayed reporting and possibly a reduction in testing; future reporting will have to confirm this.

Globally, **Influenza** and **SARS-CoV-2** are co-circulating and increasing (see Figure 1), with some countries like **South Korea, France** seeing a simultaneous increase in activity of both viruses. However in **Mexico**, **influenza** activity decreased as **SARS-CoV-2** activity increased, and this pattern may become more common as SARS-CoV-2 activity increases (see Figure 1) in other countries.

Based on an assessment of the population immunity levels in western Europe (**France, Germany, Italy, Spain, United Kingdom**) before the 2022/23 winter and Australia during the Southern Hemisphere 2022 winter, a modelling exercise estimated that countries in western Europe will experience early and moderately large influenza epidemics. This analysis also expects differences will arise in the influenza epidemics between countries, with **Germany and Spain** experiencing larger epidemics than **France, Italy and the UK**, especially in children [2].

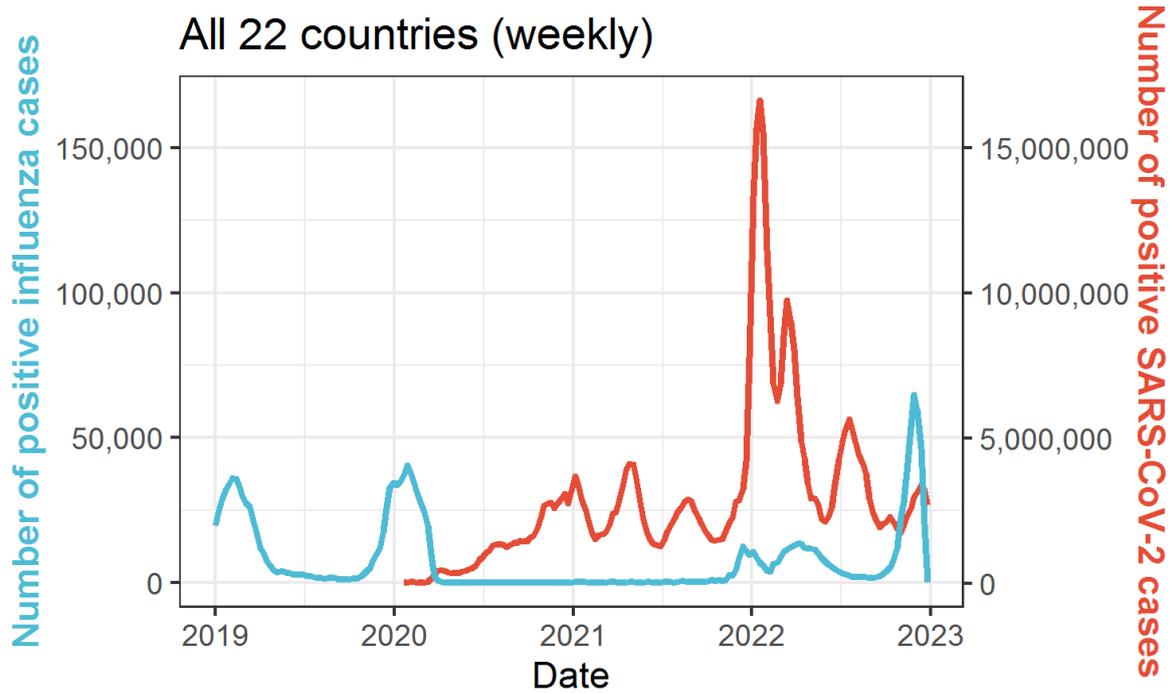

Figure 1: SARS-CoV-2 and influenza detections in the 22 countries covered by the Bulletin since 2019

Note: The apparent and sharp decrease in influenza detections in week 52 of 2022 is likely due to incomplete reporting

Monthly plots by country

The plots per country show weekly data for **influenza** and of **SARS-CoV-2** infections from January 1, 2019 up to December 18, 2022. This FluCov Bulletin includes the countries Canada, United States, Mexico, Brazil, United Kingdom, France, Germany, Italy, Netherlands, Spain, Poland, South Africa, Egypt, China, Japan, South Korea, India, Philippines, Thailand, Vietnam, Israel and Australia.

Per country, the top plot displays the number of positive **influenza** (in blue) and of **SARS-CoV-2** (in red) cases. An overview of the absolute number of **influenza** and of **SARS-CoV-2** cases per country can be found on [pages 27-28 of this FluCov Bulletin \(click here\)](#). The bar in the middle displays the Stringency Index (SI; a country-specific composite metric of the mitigation measures that are in place) over time, where light red indicates loose measures and dark red indicates strict measures. The bottom plot displays the percentage of **influenza** (in blue) and of **SARS-CoV-2** (in red) specimen testing positive

The FluCov Dashboard is live!

All Figures and Tables in the FluCov Bulletin can now be accessed (real-time) at:

^a Laboratory-confirmed cases.

^b Influenza cases are reported by FluNet on a weekly basis. To convert these data to months, weekly data are assigned to the month most days in that week belong to. SARS-CoV-2 cases are reported per day and assigned to each month by date.

Methodology

Background

After assessment of alarming levels of spread and severity of SARS-CoV-2 virus, on March 11, 2020, WHO declared COVID-19 a pandemic [3]. The emergence of this new virus has had a major impact on the global circulation of respiratory viruses, including influenza and RSV [4]. The FluCov project aims to understand and communicate the impact of COVID-19 on: i) influenza activity and ii) prevention and control measures (e.g. vaccination) in the coming years.

Scope

The countries included in this FluCov-Bulletin are distributed over the Americas (North, Central and Tropical South), Europe (Northern, South West and Eastern), Africa (Northern and Southern), Asia (Eastern, Southern, South East and Western) and Oceania. These data are compared to the prevention and control measures applied in each country using the Stringency Index from the Oxford COVID-19 Government Response Tracker (OxCGRT) [5].

Data sources

- **Influenza:** FluNet [6] is a global web-based tool for influenza virological surveillance first launched in 1997. The virological data entered into FluNet, e.g. number of influenza viruses detected by subtype, are critical for tracking the movement of viruses globally and interpreting the epidemiological data. The data are provided remotely by National Influenza Centres (NICs) of the Global Influenza Surveillance and Response System (GISRS) and other national influenza reference laboratories collaborating actively with GISRS or are uploaded from WHO regional databases.
- **SARS-CoV-2:** Our World in Data systematically collects COVID-19 data which is presented in their online tool [7]. We used this platform to extract data on the number of cases, as well as tests performed per country. This data is extracted both from the John Hopkins repository on daily confirmed COVID-19 [8] cases as well as various national public health institutions.
- **Government response tracker:** The Oxford COVID-19 Government Response Tracker (OxCGRT) [5] systematically collects information on several different common policy responses that governments have taken to respond to the pandemic on 20 indicators such as school closures and travel restrictions. It now has data from more than 180 countries. OxCGRT data is downloaded directly from the Our World in Data platform.

Extraction details

Data were extracted on 2 January 2023 and cover the period 1 January 2019 to 1 January 2023. Data from both platforms are regularly updated and **sometimes retrospectively corrected**. This might explain any discrepancies between our reported figures and the data published online, even when using data for the exact same period. In case of any unclarities or perceived irregularities, feel free to contact us at flu cov@nivel.nl.
